1 Introduction

This memo describes the Cassini RADAR activities for the 5th Titan flyby on which SAR data will be acquired. This SAR data collection occurs during the s20 sequence of the Saturn Tour. This flyby pushbrooms both ends of the SAR pointing profile to acquire more image coverage area. The altimeter track parallels the outbound T8 altimeter track which will provide a useful cross-reference. A special division is used to image the Huygens Probe landing site from an altitude of about 11,000 km. A sequence design memo provides the science context of the scheduled observations, an overview of the pointing design, and guidelines for preparing the RADAR IEB.

2 CIMS and Division Summary

Each RADAR observation is represented to the project by a set of requests in the Cassini Information Management System (CIMS). The CIMS database contains requests for pointing control, time, and data volume. The CIMS requests show a high-level view of the sequence design. Table 1 shows the CIMS request summary for this observation. Although the CIMS requests show Low-SAR intervals, in reality the radar will be operated in Hi-SAR mode throughout this flyby.

The CIMS requests form the basis of a pointing design built using the project pointing design tool (PDT). The details of the pointing design are shown by the PDT plots on the corresponding tour sequence web page. (See <https://cassini.jpl.nasa.gov/radar>.) The RADAR pointing sequence is ultimately combined with pointing sequences from other instruments to make a large merged c-kernel. C-kernels are files containing spacecraft attitude data.

A RADAR tool called RADAR Mapping and Sequencing Software (RMSS) reads the merged c-kernel along with other navigation data files, and uses these data to produce a set of instructions for the RADAR observation. The RADAR instructions are called an Instrument Execution Block (IEB). The IEB is produced by running RMSS with a radar config file that controls the process of generating IEB instructions for different segments of time. These segments

of time are called divisions with a particular behavior defined by a set of division keywords in the config file. Table 2 shows a summary of the divisions used in this observation. Table 3 shows a summary of some key geometry values for each division. Subsequent sections will show and discuss the keyword selections made for each division. Each division table shows a set of nominal parameters that are determined by the operating mode (eg., distant scatterometry, SAR low-res inbound). The actual division parameters from the config file are also shown, and any meaningful mismatches are flagged.

3 Warmup and Overview

The radar warmup rider begins at 2006-04-30T16:43:15.000 (-04:14:58.8). During the warmup, the IEB will be set to collect 1-second radiometer data on all 5 beams as shown in table 4. Div A covers the turn to Titan and may provide data on the beam spillover sidelobes.

The active mode observations begin with SAR imaging. The turn from ORS attitude to the pushbroomed ivd profile finishes at -17 min. The radar beams first intercept Titan's surface at -20 minutes, and division B runs B3 only SAR-Low mode at a reduced data rate to acquire some degraded imaging coverage during the last 3 minutes of the turn. The outbound sequence includes SAR imaging, altimetry, scatterometry, and radiometry scans. During the turn from altimetry to the start of the scatterometry scan, we take advantage of an opportunity to pass the central beam over the Huygens Probe landing site and collect some imaging data in low-res SAR mode. Tables and figures show the parameters and designs during these divisions. Refer to previous Titan flyby sequence design memos for the standard performance tradeoff analyses.

Table 5: t13 div_c standard_sar_low_inbound block

4 Div's C-K: SAR Imaging

A pushbroom profile is used on both inbound and outbound sides to extend the imaging swath. The profile is targetted from -17 minutes which is the earliest time the spacecraft could finish the turn, to 16 minutes. SAR data is also collected during the final turn to altimetry to pick up imaging during the sweep back to nadir pointing. From -17 minutes to -16.1 minutes, Div's C-H switch the radar mode back and forth between Low-SAR and Hi-SAR every 8 seconds. During this time, the two SAR modes provide a different balance between range (cross-track) and doppler (along-track) resolution. In Hi-SAR, cross-track resolution is better than along-track resolution. In Low-SAR, along-track resolution is better than cross-track resolution (see Fig. 3). Switching back and forth will let us try out a special kind of processing to enhance resolution. This is a low-risk experiment because the standard SAR processing will still work without modification. At -16 minutes one last Low-SAR division lasts until -15 minutes. At -15 minutes, Hi-SAR is clearly favored and the instrument switches to this mode for the rest of the SAR swath. Targetting of the outbound pushbroom profile ends at +16 minutes, so no Low-SAR divisions are used. SAR-Hi mode is continued during the backsweep to nadir. This extra coverage may provide some stereo opportunities. Table 5 shows a representative Low-SAR division and table 6 shows the two Hi-SAR divisions that cover the bulk of the swath.

4.1 PRF and Incidence Angle Profiles

The PRF profile and incidence angle profile (Fig. 1) are optimized for maximum usable imaging coverage. The Ta profiles were produced for a 950 km flyby which is the most common SAR flyby altitude. The T3 profiles were optimized for a 1500 km flyby. The T13 flyby will be at 1850 km altitude, and the higher altitude profile used at T3 will be used again here. The optimized profile maximizes usable cross-track width while avoiding gaps in the imaging swath. Unlike some previous SAR imaging passes, this pass will not include any PRF hopping which has not proven necessary.

Name	Nominal	j	k	Mismatch	Comments
mode	sarh	sarh	sarh	no

Table 6: t13 div_jk standard_sar_hi block

Figure 1: B3 boresight incidence angle during the time around c/a.

Figure 2: Nadir pointed B3 doppler spread during the time around c/a. Doppler spread is measured within the two-way 3 dB beam pattern.

Figure 3: SAR projected range and azimuth resolution. These values are computed from the IEB parameters and are not related to the pixel size in the BIDR file. The pixel size was selected to be always smaller than the real resolution.

4.2 SAR Resolution Performance

For all of the SAR divisions the effective resolution can be calculated from the following equations,

$$\delta R_g = \frac{c}{2B_r \sin \theta_i}, \quad (1)$$

$$\delta x = \frac{\lambda R}{2\tau_{rw} v \sin \theta_v}, \quad (2)$$

where δR_g is the projected range resolution on the surface, c is the speed of light, B_r is the transmitted chirp bandwidth, θ_i is the incidence angle, δx is the azimuth resolution on the surface, λ is the transmitted wavelength, R is the slant range, τ_{rw} is the length of the receive window, v is the magnitude of the spacecraft velocity relative to the target body, and θ_v is the angle between the velocity vector and the look direction. Figure 3 shows the results from these equations for the Ta flyby using the parameters from the IEB as generated by RMSS. The calculations are performed for the boresight of beam 3 which is the center of the swath.

Projected range increases with decreasing incidence angle, so the range resolution varies across the swath with better resolution at the outer edge. The SAR pointing profile decreases the incidence angle as time progresses and altitude increases, so there is progressive deterioration of range resolution away from closest approach. The projected range resolution rapidly deteriorates as the incidence angle decreases toward zero at the very beginning and end of the swath.

Azimuth resolution is a function of the synthetic aperture size which is determined by the length of the receive window in each burst (assuming the receive window is always filled with echos). Azimuth resolution deteriorates less quickly because the number of pulses and the length of the receive window are increased as altitude increases which mitigates the increasing doppler bandwidth of the beam patterns. The receive window length increases to fill the round trip time until the science data buffer is filled. At this point it is no longer possible to extend the receive window, and azimuth resolution starts to deteriorate more rapidly.

5 Div L: Altimetry

The parameters used by the standard outbound altimeter segment are shown in table 7. Figure 4 shows how closely the T13 outbound altimetry track and the inbound T8 altimeter tracks approach each other. Minimum separation distance is about 10 km which is much less than the pulse limited footprint size of about 25 km. The T13 altimeter track was extended in time to 38 minutes to maximize the amount of overlap with the already acquired T8 altimeter track.

Name	Nominal	Actual	Mismatch	Comments
mode	altimeter	altimeter	no	
start_time (min)	19.0	20.0	yes	
end_time (min)	30.0	38.0	yes	
time_step (s)	don't care	10.0	no	Set by valid time calculation
bem	00100	00100	no

max_data_rate	85.000	31.000	yes	leaving as much data for SAR as possible
interleave_flag	on	on	no	
interleave_duration (min)	varies	6.8	no	

Table 7: t13 div_1 standard_altimeter_outbound block

Comparing these two tracks will provide a rare cross validation of the altimeter processing and the accuracy of the time-correlation and ephemeris files provided by the project.

6 Div M: Special Imaging of Huygen's Landing Site

At the end of the altimeter track, the spacecraft turns to point beam 3 at the start of the scatterometer raster scan. The Huygen's probe landing site was near the turn track, so we elected to expend a few minutes and a few tens of Mbits of data volume to acquire more imaging coverage of this important area. The pointing design targets the probe landing site and dwells there for about 12 seconds. Division M covers this dwell and the surrounding time of slow beam movement with a SAR-Low division to acquire imaging data for 3 minutes (see table 8). SAR-low was selected because it provides the closest match between range and azimuth resolution with sufficient SNR to provide reasonable imaging performance. A PRF of 2500 Hz is used to space range and doppler ambiguities outside of the Beam 3 main lobe. Beam 3 only is used to avoid ambiguity issues, IEB command issues, and to maximize the number of looks. Figure 5 shows the iso-range and iso-doppler structure at the time when beam 3 is centered on the landing site. Beam 3 is small enough that ambiguities should not be an issue. Figure 6 shows the surface range and azimuth resolution expected during division M, and figure 7 shows the corresponding expected noise equivalent σ_0 . Both of these figures assume SAR-Low mode which provides the most optimal imaging performance.

7 Div's N,O: Scatterometry Scan

The IEB instructions for the scatterometry divisions are generated by RMSS under the control of the set of config parameters shown in table 9. Although not shown in table 9, scatterometer mode operations use a transmit-receive

Figure 4: Near overlap of T13 and T8 altimeter tracks. 1 minute point spacing. Closest approach is about 10 km.

Figure 7: Noise equivalent σ_0 during Div M using SAR-Low.

Figure 8: Outbound Scatterometry scan in target body-fixed coordinates

Figure 9: Outbound incidence angle variation during scatterometry scan

window offset (TRO) of 6 which makes the echo window 6 PRI's longer than the number of pulses transmitted. This is done to increase the valid time for an instruction by letting the pulse echos walk through the longer echo window before the range-gate needs to be updated. This is particularly important during Titan scatterometry raster scans where the number of instructions needed to track the varying range can exceed the number available if a smaller TRO value is used. The positive TRO value also guarantees noise-only data in each burst which eliminates the need to insert special noise-only bursts. The PRF of 1.2 KHz is high enough to cover the doppler spread within beam 3, so doppler sharpening could be performed.

During Ta, the scatterometry scans suffered from clipping during the center of the scan lines. The clipping occurred because RMSS placed all of the instruction boundaries near the outer edges of the scan where they were most needed to track the rapidly varying range. Thus, the auto-gain algorithm did not have an opportunity to see the higher signal levels near the center of the scan lines where the incidence angle dropped close to nadir pointing. To prevent this problem from recurring, auto-gain will not be used for scatteromtry raster scans. Instead, a fixed attenuator value will be used to keep the signal on-scale over the whole raster scan. Based on experience with T3, a 15 dB attenuator setting will be used for scan lines that go below 10 degrees incidence. For T13, all of the scan lines remain above 20 degrees incidence, so the 9 dB attenuator setting is used throughout.

8 Div's P: Radiometry

At the end of this observation, two pairs of radiometer scans will be performed. Due to data volume and instruction count constraints we will not attempt any compressed scatterometry during the radiometry scans. The parameters for the radiometry scans are shown in table 10.

9 Revision History

10 Acronym List

AL	Acronym List
ALT	Altimeter - one of the radar operating modes
BAQ	Block Adaptive Quantizer
CIMS	Cassini Information Management System - a database of observations
Ckernel	NAIF kernel file containing attitude data
DLAP	Desired Look Angle Profile - spacecraft pointing profile designed for optimal SAR performance
ESS	Energy Storage System - capacitor bank used by RADAR to store transmit energy
IEB	Instrument Execution Block - instructions for the instrument
ISS	Imaging Science Subsystem
IVD	Inertial Vector Description - attitude vector data
IVP	Inertial Vector Propagator - spacecraft software, part of attitude control system
INMS	Inertial Neutral Mass Spectrometer - one of the instruments
NAIF	Navigation and Ancillary Information Facility
ORS	Optical Remote Sensing instruments
PDT	Pointing Design Tool
PRI	Pulse Repetition Interval
PRF	Pulse Repetition Frequency
RMSS	Radar Mapping Sequencing Software - produces radar IEB's
SAR	Synthetic Aperture Radar - radar imaging mode
SNR	Signal to Noise Ratio
SOP	Science Operations Plan - detailed sequence design
SOPUD	Science Operations Plan Update - phase of sequencing when SOP is updated prior to actual sequencing
SSG	SubSequence Generation - spacecraft/instrument commands are produced
SPICE	Spacecraft, Instrument, C-kernel handling software - supplied by NAIF to use NAIF kernel files.
TRO	Transmit Receive Offset - round trip delay time in units of PRI
